Month 9

The Sentiment Effect :-

When are Buying or Selling Probabilities Highest :-

→ For Day Trades - The use of Asian Range and opening price are key.
- Bearish short Days :- Ideally Above the opening Price and/or Asian range high.
- Bullish Long Days :- Ideally below the opening Price and or Asian range low.

→ The market will have a short term shift in "sentiment" and less informed traders will chase price on the impulse or initial swing intraday.

→ Focusing on strict conditions like Daily or 4H direction based on institutional orderflow and combining PD Array Matrix for next level objectives, will provide you the highest probability setup.

→ We wait to enter an opposing Market Direction - for high odds setups.

Buy conditions: Proper setup for Long Entries :-

→ IPDA suggests a Daily or minimum 4H discount Array is in play.
→ There is a sufficient range in pips between Market Price & opposing Premium Array found on the daily or minimum 4H chart.
→ Price declines under the "opening Price" and the Asian Range low.
→ Ideally the decline under the Asian Range low will be a logical Discount Array on 15min timeframe.
→ Typically Price will not spend much time at the discount array on the 15 Min.
→ The longer price stays or hovers near the 15 min Discount Array - odds drop.
→ Short term sentiment will be most bearish at the time we enter long trades.

Use a 10 period W%R for Sentiment.

& Vice Versa for sell conditions.

Filling the Numbers :-

IPDA looks to fill four Numbers Daily :-

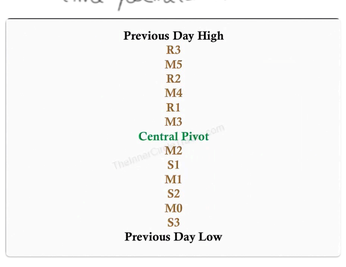

→ The Daily Range will seek to fill or "trade to" four specific level each day.
→ Previous day's high or low
→ Above the central Pivot: (CAMTO Pivots)
- M3 = Mid Point or 50% of the distance b/w CPP & R1.
- R1 = Resistance level for staged orders.
- M4 = Mid Point or 50% of the distance b/w R1 & R2.
- R2 = Resistance level for staged orders.
- M5 = Mid-Point or 50% of distance between R2 & R3.
- R3 = Resistance level for staged orders.

Staged means there are buyers & sellers there

→ Below the central Pivot :-
- M2 = Mid Point of 50% of the distance b/w CPP & S1.
- S1 = Support level for staged orders.
- M1 = Mid Point of 50% of distance b/w S1 & S2.
- S2 = Support level for staged orders.
- M0 = Mid Point or 50% of distance b/w S2 & S3.
- S3 = Support level for staged orders.

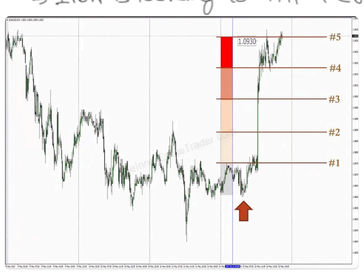

→ Using the orderflow direction and PD array Matrix for specific bias.
→ The entry points you use for the trades you look for the numbers that will fill in:
- If Long Entry - look above your entry point for the sequential four levels above.
- If short Entry - look below your entry point for the sequential four levels below.

→ On large range days - more than 4 levels can be filled.
→ The tendency to move atleast four levels is a general rule of thumb.
→ Ideally, Majority of your trade position will be taken off after four levels fill.
→ Leave a Portion on for Potential for a large range day - time permits it.

→ Utilizing the CBDR when you're shorting the market - selling above the CBDR you count the low of the CBDR as level one of four to fill.
→ Expect the market to trade down to four CBDR lows. & Vice Versa for buying.
→ IPDA is looking to fill 4 CBDR Range.

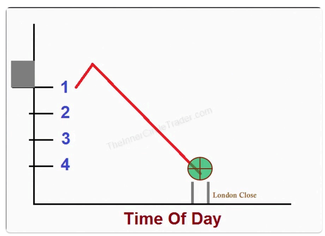

→ Utilizing the Flout when you're shorting the market - shorting above the Flout Equilibrium - you count the Equilibrium of the Flout Range to the high as one standard deviation. The Equilibrium of the Flout Range to the low is one Standard deviation.
→ The total Flout Range is projected on the basis of 50% of its complete Range - between 3:00 PM in New York and Midnight in new York.
→ Expect the Market to trade down to four Flout Range Lows
→ Vice Versa for buying.

Which Numbers Do You focus on :-

→ When considering which "numbers to fill" - consider the fact that we do no ever know certain which levels IPDA will use before the trading day begins.
→ We can get closer to the truth as the trading day completes.
→ The New York session will generally provide the measurements IPDA is presently using for the engineering of the daily Range.
→ We look for confluences between one or possibly more of the tools we measure for the four levels. Coupling these with the present trading environment, time of day, direction & PD array Matrix... you will unlock likely daily high or low.

20 Pips Per day :-

Targeting 20 pips per day :-

→ You will not make 20 pips everyday... period.
→ Ideally you want to bank 20 pips in any day trade you take.
→ However, there are few techniques one can use a ferret out a 20 pip scalp almost everyday. [Emphasis... "almost"]
→ The Trader still needs to do their homework and determine what the current market environment is. Consolidation, Reversing, Expanding.
→ This lesson we will teach two methods I like to scalp & aim for 20 pips.

Trading the 15 Min NY Session Stops :-

(Yen, Aus, Kiwi Crosses)

→ Buy setup :- During the Asian session up to 12:00 AM NY time scout short term lows formed in the New York session - Trading long after Asia Probed the lows.
→ Sell setup :- During Asian session up to 12:00 AM NY time scout short term high formed in the New York session - trading short after Asia probed the highs.

Timing by way of 5 minute chart. Target is 20 pips fixed & Stop 20 pips.

Trading the New York Expansion :-

→ Buy setup : During NY session up to 10:00 AM NY time scout short term lows formed in New York open - trading lows after New York probed the lows while london session posted Daily low and 5 day ADR pending.
→ Sell setup : Vice versa of Buy setup.
→ Timing by way of 5 minute chart. Target is 20 pips fixed. Stop 20 pips.

Trading in Consolidations :-

The Secret behind consolidations :-

→ Retail traders :- will look out for breakouts to establish a directional "bias".
Smart Money :- will engineer or fade breakouts of a consolidation.

→ Retail Traders :- Buys the previous Low & sells the previous high.
Smart Money :- Buys under old low & sells above old high
→ Retail traders :- chase expansions that originate from the equilibrium.
Smart Money :- fade the expansions that originate from the equilibrium.

& Smart Money sells the breakout. & Vice Versa

Trading Market Reversals :-

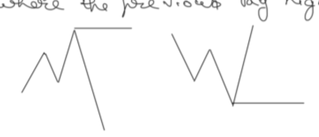

Eight Reversals that can be traded Effectively :-

→ Previous Day's highs - Raid buy stops & Reverse.
→ Previous Day's Low - Raid sell stops & Reverse.
→ Intra week high - Raid Buy stops & Reverse.
→ Intra week low - Raid sell stops & Reverse.
→ Intermediate Term high - Raid Buy stops & Reverse.
→ Intermediate Term Low - Raid sell stops & Reverse.
→ New York Session Reversals
→ London Close Reversals.

Trading Previous Day's high's & lows :-

There are two circumstances when taking the move in Price beyond a Previous Day's Range :-

During Expansion swings there are smaller Retracements that typically create opportunities where the previous day low is raided then Price Rallies higher. In opposing Expansion swings there are retracements that create opportunities where the previous day high is raided & then declined.

→ In this example we see Price was moving higher as a part of larger expansion swing. During normal retracement lower - into a fair value Gap - Price finds buyers under the previous Daily low.
→ Using the Previous daily low and anticipating a Market Reversal after the PDL is raided - one can be buyer intraday.
→ We look for confluences of PD Arrays to support the idea of Buying under a PDL. We do not buy under a PDL on sole basis Price moves beyond the Previous Day's Low.
& vice versa for Previous Day's high.

Trading Intra week highs :-

In this example we see Price was trading above the Equal highs on thursday of this particular week. Price raided the buy stop liquidity Pool as a Premium array.

Using the Intra-week high and anticipating a Market Reversal after the buy stops are raided - one can be seller intraday.

We look for confluences of PD Arrays to support the idea of selling above an Intra week high. We do not sell above a high on sole basis Price moves beyond the Previous Intra-week high. & vice versa for Intra week Lows.

Trading Intermediate Term Highs & lows :-

→ In this example we see price was trading in large consolidations. The periods when the market is not trending one direction offer ideal conditions - for shorting above an old high & Buying below an old low - from previous week or longer in time.
→ Studying old highs & old lows and incorporating the PD Array Matrix can assist you in finding higher odds day trades. These setups tend to present the most dynamic reactions and that is always a bonus in trading intraday.
→ The lack of directional trend environments occurs more often than not. Traders that identify this range bound condition will have little to fear when fading the moves beyond old Range extremes.

New York session Reversals :-

→ Using the weekly templates provided to you and studying the current Market structure - one can Anticipate the New York session reversal.
→ While a reversal can occur on any day of the week we learn that certain weekly templates are more likely to unfold over another.
→ Knowing the HTF PD Arrays and the IPDA data ranges the market is presently respecting - scenario's can be outlined in our analysis. If there is a HTF Discount Array that is below the market price but has yet to be met. The day it trades down into it during london's move and crossed over to new York open - this is classic New york session Reversal conditions. Reverse for bearish conditions.

London close Reversals :-

→ London close can be used for intraday reversals on large range days for scalps. The large range day that exceeds its 5 ADR tends to retrace about 20% of its total daily range at 10:00 AM to Noon NY Time.
→ In longer term conditions, the london close can time a Market Reversal that can lead to a series of days of one sided direction. This is best determined with the use of weekly templates and study of the current Market structure.
→ As seen in this example the reversal occurred on the Wednesday and at london close. This price occured at a HTF Discount Array and was expected to trade higher as a result. London like NYO, can reverse the market.
