# Bread & Butter Buy setups :-

## Daily opportunities in scalping :-

In buy programs IPDA will perform one of two price engine models.

1. Accumulate Sell side Liquidity by repricing under an old low.
   - Sell stops will be triggered inducing counterparty sellers to pair long entries with.
   - Price will seek a higher short term premium Array to offset positions.
2. Reaccumulate fair value in retracements lower at Discount Arrays.
   - Weak long holders will be squeezed in the retracement lower.
   - Price will seek to expand higher to a short term Premium Array to offset positions.

## Offset Accumulation :-

→ IPDA will reprice the market below an old low to promote sell stops that would be resting there for current long holders. This is essence "engineers" sellers at deep discount prices. The open float below that old low may also have sell stops for breakout systems that wish to sell on weakness.

→ This model is called Offset Accumulation. It's primary purpose is to "offset" current long holders and or induce more sellers at discount pricing. The model is seen frequently in bullish market conditions and while HTF institutional order flow is suggesting higher prices.

→ Typically, Offset Accumulation models unfold quickly and you must learn to anticipate them at key lows intraday.

## Reaccumulation :-

→ IPDA will reprice the market lower to a fair value price array to provide smart money discount pricing for long entries. The Market will be bullish from an Institutional perspective and many times unfolds after a recent sell stop raid. The retracement lower in price will place pain on current long holders & tends to induce selling - thus providing Sell side Liquidity to pair smart money long entries with.

→ This model is called Reaccumulation. It's primary purpose is to "Reaccumulate" new long entries and or induce more sellers at discount pricing. The Model is seen frequently in Bullish Market conditions & while HTF institutional order flow is suggesting higher prices.

→ Typically, Reaccumulation Models unfold quickly and you must learn to anticipate them at key Discount Arrays Intraday.

## Realistic objectives :-

Trade Duration :- Typically 1-2 hour or less

Pips per trade :- 15-30 Pips on average

Timing chart Interval :- 5 Minute

Frequency of setups :-

Per week :- as many as 15 or more

Per Day :- 2 to 3 setups typically

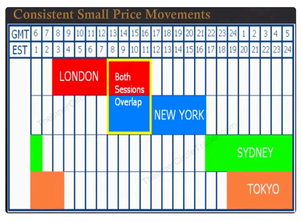

Per Session :- 1 per Session [London, New York, London close, Asia]

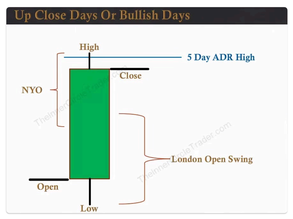

Risk to Reward :- typically 1:1 but some can be better than that

Ideal Risk per trade :- 0.5% to 1%

## Killzone specific :-

- All scalping should be done during the ICT Killzones. Since the duration and style of trading is so short term in nature, we need the most volatile times of the trading day to ensure we "get a move".
- There are times when using limit orders on entry may execute outside a Killzone. This tends to happen in London lunch or post New York open. It is best to be actively following the bar if we are going to scalp Intraday.

## Revisiting the Daily Range :-

→ When the market is poised to trade higher based on HTF institutional order flow - in essence we expect the open to be at or near the low of the daily range.

→ There can be small decline below the open Price.
(0 GMT open & Midnight New York)

→ London open posts the inital leg higher Intraday then waits for NYO.

→ NY open seeks a continuation higher in price to 10:00 AM NY time.

→ Between 10:00 AM and Noon in New York time we expect high of the daily range to form and at 5 day ADR Projected high.

→ Price will normally Retrace lower and close off the high of the day.

## The London open :-

→ When HTF Institutional order flow is Bullish we Anticipate London session low of day formation.

→ The open at 0 GMT or 12 AM in New York can see a retraction phase lower in price. This can be scalped from the open or just above it - prior to 1:00 AM New York time.

→ The classic London Judas Swing lower can be scalped even easier.

→ The market retraces between 5:00 AM and 7:00 AM NY time - and this can provide a long scalp entry - once a discount Array is hit.

→ Even after the ideal Judas entry point has passed - a 5 minute retracement can be entered long on to scalp the remainder of London open to 5:00 AM New York time.

## The New York Session :-

→ When london open confirms Institutional sponsorship on the long side and posts the daily low - we expect to see New York open to continue higher - unless a HTF Premium Array has been hit intraday and or ADR is reached.

→ We look for the intraday swings higher to determine discount range arrays to go long at in the NYO Killzone.

→ Using the 8:20 AM New York time for CME open to anticipate the New York Judas swing to take.

→ Targets will be 5 day ADR high and the Next HTF Premium Array found on a 4H, 60 Min basis.

→ If ADR high is reached prior to 10:AM - take 80% off & leave a small portion on to capture any range expansion that might fill

## The London close :-

→ When the New York and London sessions have moved in tandem and the 5 day ADR high has been reached & it is atleast 10:30 AM NY time to expect a retracement off the day's high 10:30 AM to 12:00 PM.

→ Ideally Price should exceed the 5 Day ADR Range.

→ Look for a 5 Minute failure swing at the high & a Bearish order block to enter on.

→ Risking 10 pips above the Day's high and target 20 to 30% of the total daily range in a retracement lower.

→ Keep in mind this trade can be very difficult to see han out some days as the range can or could extend far more than ADR high.

→ Ideally take 1:1 target based on required stop - no more than 20 pips.

## The Asian open :-

→ When the Market is Bullish - we can enter a long at or just under 0 GMT open price and expect an expansion 15-20 pips higher as the Asian Range is established.

→ Asian sessions can be traditionally very Narrow and while this trade has proven profitable in the past - like london close trades - we are looking at the lowest volatile periods of the daily range formation.

→ Always aim for 15-20 pips in this session as the range can be limited on the basis it will be the Asian Range formation.

→ Take full exits on scalp in this time of day.

→ Its not optimal to expect a second leg in price. Avoid greed here and if you're fortunate to get 20 pips - be content & exit.

## Bread & Butter sell setups :-

Vice versa of Bread & butter Buy setups.

## The Average Daily Range :-

→ The ADR does not have to fill for the day.

→ ADR can be expected to act as ½ of the actual ADR in some conditions:
- When a longterm trend is underway and a intermediate term swing has begun - a large impulse swing can surge the daily range twice the ADR especially when the ADR is under 60 pips.
- When a intermediate term swing is completing at a HTF Array & on the strength of high Impact news - capitulation.

→ ADR not filled at NY open but during london close are ideal.

→ If ADR fills at or before NY open - ADR will likely be exceeded - if high impact news is due out after equities open.

## The Scalping Model :-

→ Essentially the setups are Micro-setups on the 5-Minute chart, we outline on the HTF charts.

→ The elements of Time of Day are essential to framing the Intraday price swings in every daily ranges.

→ The HTF PD Arrays will draw price and Intraday the LTF PD Arrays will provide the timing & price levels to enter on.

→ Ideally we use scalps to fill in slow periods or enter trades that may have already started and the lowest risk entry has long passed.

→ If you spend your time studying whether the HTF is moving higher or lower & wait for small range days to form - the market will reward your patience and supply you with daily ranges that expand and form clear Intraday swings perfect for scalping.

# ICT Daily Day Trade Routine :-

## Forex Factory :-

→ High Impact & Medium Impact news for the day in London & NY Killzone

## US Dollar Index :-

→ Look for last trading day for IPDA data ranges & remove sundays.

→ Look for fibonacci, PD Arrays.

→ IPDA ranges are dynamic, we add new candle & remove previous candle. → move the Rectangle with da

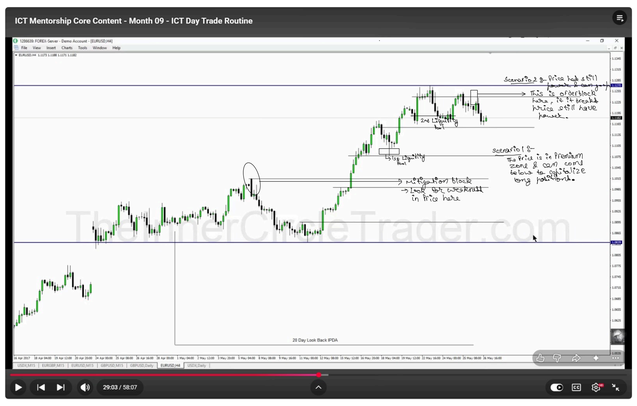

→ For day trading, we're gonna operate in last 20 days. If we've exhausted all PD Arrays then move to last 40 days.

**ICT Day Trading Daily Routine**

- Determine The Economic Calendar Impact For Today
- Narrow Focus To Killzone News Releases Highor Medium
- Determine Daily Institutional Order Flow Of USDX
- Locate the USDX Daily PD Arrays In IDPA Data Ranges
- Consider If USDX Is Moving From Premium Or Discount
- Using The News Due Out - Focus On That Pair Intraday
- Determine The Daily Institutional Order Flow Of Pair
- Locate the Pair's Daily PD Arrays In IPDA Data Ranges
- Confirm The Pair Is Moving From An Opposing PD Array
